The Leaderboard

Paste any old website you find. It gets audited on its own, ranked against every lead you already have, and the list keeps reordering itself as things change. A plan for Evolve OS, October 16, 2026.

My take

Yes, build it, and call it the Leaderboard. Four things shape how it should work.

- **It should not be a second list.** You already have 268 saved leads and a nightly engine that reads sites like a phone does and scores them out of 100. A site you paste should go through that same check and land in that same ranking, so a hot site you spotted on Tuesday can outrank something the engine found last week.
- **The check has to run on GitHub, not inside the board.** The board cannot open other websites, and the Claude nightly tasks are blocked from them too. The GitHub half of your engine is the only part with the open internet, and it already has the audit code. So a paste becomes a small job for GitHub, and the answer comes back to the board.
- **Be honest about "probability".** Right now there is not enough call history to say "38 percent chance". The rank starts as the engine score plus the judge's tier, shown as Strong, Good or Long shot. Once 20 or so calls have been logged, the board starts showing the real meeting rate for each band, and the weights get tuned from that, with you approving any change.
- **Sites you find yourself are worth flagging.** You only paste something because you saw a reason. Those rows get a small "You found it" mark, so you can tell them from the engine's finds. Whether that also lifts the score is your call.

How a paste works

Step	What happens	Where
1. Paste	You paste a link into the bottom bar, or into a box at the top of the Leaderboard. The board checks whether that site is already saved. If it is, it tells you where it sits ("already on the board at #12") and stops there.	Evolve OS
2. Queued	A new row appears straight away at the bottom of the board, marked as being checked. A small request file goes into the Lead Engine folder in your Google Drive.	Evolve OS, Drive
3. Audited	A new GitHub job checks that folder through the day. It reads the site the way a phone does, looks the business up on Google for the phone number, rating and review count, scores it out of 100, and opens it in a real phone browser to confirm the faults. The result goes back into the same folder.	GitHub
4. Judged	When you next open the board, it picks up the result, runs it past the same rubric the nightly judge uses (A, B, C or drop, with a one line reason and the opening fact), and writes the full lead. If you do not open the board, the 1:13 AM task does it instead.	Evolve OS, nightly task
5. Ranked	The row moves to its place on the Leaderboard. A short note says where it landed.	Evolve OS

Timing: about 30 minutes from paste to ranked during the day, depending on which option you pick below. Nothing about it ever calls, emails or texts anyone, and it never touches the calendar.

What decides the rank

The same five parts the engine already scores, out of 100, then adjusted by things that change from day to day. That is what keeps the order moving.

Part	Out of	What earns points
Need	30	No mobile layout, no tap to call, no form or booking, ads pointing at a page with no form, footer copyright 4 or more years old, not secure, very thin homepage.
Ability to pay	25	The kind of trade, Google review count, running ads, offering financing, hiring.
Reason to act now	20	A ribbon cutting or permit, "now open" or "new location" on the site, hiring, a poor Google rating with real reviews.
Reachable	15	Auburn and Opelika score highest, then nearby towns. A phone number on file. Not a chain.
Other work	10	Trades that also buy photo and film, and sites with no video at all.

Daily movement on top of the score:

- The judge's tier sets the band. A sits above B, and C or drop leaves the board.
- A call by date coming up pushes a lead up as it gets close.
- A trigger loses its pull as it ages. A ribbon cutting from last week matters more than one from March.
- Each unanswered call drops it a little, so the same names do not sit on top forever.
- Logged outcomes move it: "wants a concept" goes to the top, "not now" parks it until its date.
- New leads come in from the nightly sweep and from your pastes. The top five feed the call sheet, as now.

What you see

- A Leaderboard at the top of Pipeline. It shows the top 10, with a button to see everything ranked.
- Each row shows its place, how far it moved since yesterday (up 3, down 1, new), the business and town, the score, the band (Strong, Good, Long shot), and the one fault to open with.
- Tap a row to see why it ranks there: the five parts as bars, the facts the audit found, and the date it was checked.
- One tap on a row to put it on the call sheet, build a concept, or park it.
- Filters for Local only and You found it.
- On a phone it is one column with big rows, built the same way as the phone pass this week.

Any new wording on screen comes to you as a screenshot first, as always. The labels above are suggestions.

The build, in order

#	What gets built	Done when
1	**The GitHub job.** A new command in the engine that audits one site by its link: it reads the page, looks the business up on Google, scores it and runs the phone browser check. A new workflow runs it on a timer and reads its requests from the Drive folder.	A test link pasted into the Drive folder comes back scored, matching what the nightly sweep would say about the same site.
2	**Paste on the board.** The bottom bar notices a pasted link, and there is a paste box on the Leaderboard. It checks for repeats, saves the queued row and writes the request to Drive. This adds Google Drive to the board's connections, so the first paste asks your permission once.	A link pasted on your phone shows as queued, and its request file is in Drive.
3	**Judge and place.** The board reads finished results, runs the rubric, and writes the lead in exactly the shape the nightly engine writes. The 1:13 AM task gets one added step, so nothing waits on you opening the board.	A pasted site appears ranked, with a tier, a reason and an opening fact, and no field differs from a nightly lead.
4	**The Leaderboard itself.** The ranking, a daily snapshot so the board can show movement, the rows, the why panel, the filters and the phone layout. The call sheet keeps reading from the same order.	The top 10 matches the call sheet order, and tomorrow's board shows who moved and why.
5	**Learning from calls.** Once 20 calls are logged, it shows the real meeting rate for each band, and suggests weight changes for you to approve.	You can see whether Strong really books more meetings than Good.

Steps 1 to 3 make pasting work end to end, and each one gets tested before it goes live. Step 4 can follow straight after. Step 5 waits for real call history.

Costs, limits and honest notes

- **No model reads the websites.** That is what cost 16.8 million tokens in one night before. The audit is plain code on GitHub. The model only judges a short summary, one quick call per site.
- **GitHub minutes.** Each timed check costs about a minute, even when there is nothing to do. Checking every 30 minutes from 7 AM to 11 PM comes to about 1,000 minutes a month. GitHub's free plan includes 2,000 minutes a month for private repositories. I have not checked which plan your account is on, so that is worth confirming.
- **Google Places.** Each paste uses one search. The current sweep uses about 250 a month against a free allowance of 1,000.
- **Some sites block machine reads.** Those come back as "could not read, check it on your phone" and sit low until someone looks. They never get marked as faulty on a guess.
- **Chains and franchises** get dropped by the rubric, with the reason shown, so you know why something you pasted did not make the board.

What I need from you

One thing first: how quickly a pasted site should come back ranked. I am asking that in the chat now. After that I will ask whether you want "You found it" to add to the score, and then I will show you the wording on screen before anything goes live.
